SEPTEMBER, 1966

UNIVERSITY OF ALBERTA
FACULTY OF GRADUATE STUDIES

The undersigned certify that they have
read, and recommend to the Faculty of Graduate Studies
for acceptance, a thesis entitled "EXPLICIT ESTIMATES
FOR SOME FUNCTIONS OF NUMBER THEORY", submitted by
ROBERT A. MacLEOD in partial fulfilment of the
requirements for the degree of Doctor of Philosophy.

ABSTRACT

An integer is called square-free, or quadratfrei, if it is not divisible by the square of any prime. In the first chapter we

use known estimates for $M(x) = \sum_{n \leq x} \mu(n)$ to investigate the function

$Q(x) = \sum_{n \leq x} |\mu(n)|$, the number of square-free integers less than

or equal to x . A typical result is

$$|Q(x) - \frac{6}{\pi^2} x| \leq \sqrt{3} \left(1 - \frac{6}{\pi^2}\right) \sqrt{x}$$

for all x , with equality only at $x = 3$.

In the second chapter, with the help of the results in the first, we obtain a new estimate for $M(x)$, namely

$$|M(x)| < \frac{1}{80} x, \quad \text{for } x \geq 1114.$$

We apply this estimate to examine the sum $g(x) = \sum_{n \leq x} \frac{\mu(n)}{n}$. In

particular we show that whereas $g(x)$ changes sign infinitely often,

$g_1(x) = \sum_{14 \leq n \leq x} \frac{\mu(n)}{n}$ is always positive.

In the third chapter, we examine the function $\Phi(x) = \sum_{n \leq x} \varphi(n)$

where $\varphi(n)$ is Euler's function. We show that $\frac{\Phi(x)}{x^2}$, which is

(ii)

asymptotic to $\frac{3}{2\pi}$, takes on its minimum (over all positive integers) at $x = 1276$, the second integer x for which $\Phi(x) - \frac{3}{2\pi} x^2$ is negative.

ACKNOWLEDGEMENTS

I am indebted to my supervisor,
Professor Leo Moser, for his interest, encouragement,
and advice, and to my fellow students in number theory
for numerous discussions of the material herein contained.
Thanks also are due to Dr. J. W. Moon, who has eliminated
uncounted barbarisms from the original manuscript.

I should like to thank the following for
providing financial support: the University of
Alberta, the National Research Council, and the
Francis F. Reeve Foundation.

CHAPTER 1

SQUAREFREE INTEGERS

1. Introduction. An integer n is said to be k -free if $d^k | n$ is false for every integer $d \neq \pm 1$ (when $k = 2$, the terms 'square-free' and 'quadratifrei' are normally used). We shall restrict our attention henceforth to positive integers.

Let q_n denote the n^{th} square-free integer, and $Q(x)$ the number of squarefree integers less than or equal to x . Then

$$Q(x) = \sum_{n \leq x} |\mu(n)| ,$$

where $\mu(n)$ denotes the Möbius function. We shall give a brief survey of known results on q_n and $Q(x)$, and then proceed to examine the difference $Q(x) - \frac{6}{\pi^2} x$.

2. Survey of results. From the simple result that

$$Q(x) = \frac{6}{\pi^2} x + O(x^{1/2}) \tag{1.1}$$

(we shall prove stronger results later) it follows that

$$q_{n+1} - q_n = O(n^{1/2}) . \tag{1.2}$$

In 1941, E. Fogels [8] improved this to

$$q_{n+1} - q_n = O(n^{2/5 + \epsilon}) \quad \text{for every } \epsilon > 0. \quad (1.3)$$

K. F. Roth [22], using an argument which he attributed to Estermann, showed that

$$q_{n+1} - q_n = O(n^{1/3}) \quad (1.4)$$

and upon strengthening the argument was able to obtain

$$q_{n+1} - q_n = O(n^{3/13} (\log n)^{4/13}) . \quad (1.5)$$

H.-E. Richert [20] improved this to

$$q_{n+1} - q_n = O(n^{2/9} \log n) . \quad (1.6)$$

Using slightly different arguments R. A. Rankin [19] obtained

$$q_{n+1} - q_n = O(n^{\gamma + \epsilon}) \quad \text{where } \gamma = 0.22198 \dots . \quad (1.7)$$

H. Halberstam and Roth [10] have generalized the argument giving $q_{n+1} - q_n = O(n^{1/3})$ to obtain the following: if $q_k(n)$ denotes the n^{th} k -free number, then

$$q_k(n+1) - q_k(n) = O(n^{1/(k+1)}) . \quad (1.8)$$

In the other direction, P. Erdos [4] has shown that, for infinitely many i ,

$$q_{i+1} - q_i > (1 + o(1)) \frac{\pi^2}{6} \frac{\log q_i}{\log \log q_i} . \quad (1.9)$$

He states that it appears to be very difficult to improve on the constant $\frac{\pi^2}{6}$, and suggests that it may indeed be that, for $i > i_0$,

$$q_{i+1} - q_i < (1+\epsilon) \frac{\pi^2}{6} \frac{\log q_i}{\log \log q_i} \quad \text{for every } \epsilon > 0 . \quad (1.10)$$

He also conjectures that, for every α ,

$$\sum_{q_{k+1} < x} (q_{k+1} - q_k)^\alpha = c_\alpha x + o(x) . \quad (1.11)$$

This, if true, would imply

$$q_{n+1} - q_n = O(n^\epsilon) , \quad \text{for every } \epsilon > 0 , \quad (1.12)$$

but he can prove it only for $\alpha < A$, where A is a constant between 2 and 3.

R. Bellman and H. N. Shapiro [1] consider a slightly different problem, and obtain the following results:

1. If $\varphi(x)$ is any function such that $\lim_{x \rightarrow \infty} \varphi(x) = \infty$, then for almost all n the interval $(n, n+\varphi(n))$ contains a squarefree integer.

2. If $\varphi(x)$ is any strictly monotone function such that $\lim_{x \rightarrow \infty} \varphi(x) = \infty$, then $Q(n, n+\varphi(n))$ has normal order $\frac{6}{\pi^2} \varphi(n)$; that is, for every $\epsilon > 0$ and $n > n(\epsilon)$,

$$(1-\epsilon) \frac{6}{\pi^2} \varphi(n) < Q(n, n+\varphi(n)) < (1+\epsilon) \frac{6}{\pi^2} \varphi(n) \quad (1.13)$$

where, of course, $Q(n, n+\varphi(n))$ denotes the number of squarefree integers between n and $n+\varphi(n)$.

In a different direction, E. Cohen and R. L. Robinson [3] have examined the distribution of k -free integers in residue classes. They have shown that the k -free integers are equi-distributed (mod h) if and only if every prime factor of h divides h at least to the k^{th} power. (A set of integers is said to be equi-distributed (mod h) if the density is the same in each residue class (mod h) where the integers occur at all.)

T. Estermann [6] found that the number of representations of n as the sum of two square-free integers is

$$cn\rho(n) + O(n^{2/3} + \epsilon) \quad (1.14)$$

where $c = \prod_p (1 - \frac{2}{p^2})$ and $\rho(n) = \prod_{p^2 | n} (1 + \frac{1}{p^2 - 2})$. Cohen [2] was able to improve the error term to $O(n^{2/3} \log^2 n)$.

Considerable work has been done on pattern problems for square-free integers. W. Sierpinski [26] showed in 1959 that, for infinitely many k , the integers $4k+1$, $4k+2$, and $4k+3$ are all square-free. I was able to generalize this to show that any pattern of square-free and non-square-free integers which occurs at all in the sequences of integers occurs infinitely often. However, considerably sharper results

had been discovered by S. S. Pillai [17] in 1936 and L. Mirsky [14], [15] in 1948 and 1949, but apparently overlooked by Sierpinski. They are the following.

Let d_1, d_2, \dots, d_{r-1} be a fixed set of positive integers, and for any prime p let $g(p)$ be the number of different residue classes mod p^2 among $0, d_1, d_2, \dots, d_{r-1}$. Let $N(x)$ be the number of positive integers t such that $t, t+d_1, \dots, t+d_{r-1}$ are all squarefree and $\leq x$. Pillai showed that

$$N(x) = Ax + O\left(\frac{x}{\log x}\right) \quad (1.15)$$

where $A = \prod_p \left(1 - \frac{g(p)}{p^2}\right)$. In particular, for $r = 2$, $d_1 = 1$, $d_2 = 2$ (i.e. for Sierpinski's problem) $A = \prod_p \left(1 - \frac{3}{p^2}\right) \approx 0.12$ so that for about half of all k 's the integers $4k+1$, $4k+2$, and $4k+3$ are all square-free.

Mirsky generalized Pillai's results as follows: let

$a_1, \dots, a_\ell; b_1, \dots, b_m$ be any distinct positive integers; let $H(x) = H_r(x; a_1, \dots, a_\ell, b_1, \dots, b_m)$ be the number of systems of positive integers $n+a_1, \dots, n+a_\ell; n+b_1, \dots, n+b_m$ not exceeding x and such that the first ℓ are r -free while the remaining m are not. Then

$$H(x) = hx + O(x^{2/(r+1)} + \epsilon) \quad , \quad (1.16)$$

$$\text{where } h = \begin{cases} 0, & \text{if } D(p^r; a_1, \dots, a_\ell) = p^r \text{ for some } p \\ h_r(a_1, \dots, a_\ell; b_1, \dots, b_m) = \sum_{k=0}^m (-1)^k \sum_{1 \leq v_1 < \dots < v_k \leq m} \prod_p \\ \left\{ 1 - \frac{D(p^r; a_1, \dots, a_\ell; b_{v_1}, \dots, b_{v_k})}{p^r} \right\} & \text{otherwise,} \end{cases}$$

and $D(\sigma; n_1, \dots, n_s)$ denotes the number of different residue classes mod σ represented by n_1, n_2, \dots, n_s . As a special case, consider blocks. By a block of s integers with respect to a class C , we mean a sequence of s consecutive integers, say $n, n+1, \dots, n+s-1$, in C , while $n-1$ and $n+s$ are not in C . Let $Q_{r,s}(x)$ denote the number of blocks of s r -free integers $\leq x$ and $V_{r,s}(x)$ the number of blocks of s r -integers (i.e. non- r -free integers) $\leq x$. Then

$$(i) \text{ for } r \geq 2, s \geq 2^r, Q_{r,s}(x) = 0;$$

$$(ii) \text{ for } r \geq 2, 1 \leq s \leq 2^r - 1, Q_{r,s}(x) = q_{r,s} x + O(x^{2/(r+1)} + \epsilon)$$

where

$$q_{r,s} = \begin{cases} \prod_p \left(1 - \frac{s}{p^r}\right) - 2 \prod_p \left(1 - \frac{s+1}{p^r}\right) + \prod_p \left(1 - \frac{s+2}{p^r}\right), & 1 \leq s \leq 2^r - 2, \\ \prod_p \left(1 - \frac{2^r - 1}{p^r}\right), & s = 2^r - 1, \end{cases}$$

$$(q_{r,s} > 0);$$

$$(iii) \text{ for } r \geq 2, s \geq 1, V_{r,s}(x) = v_{r,s} x + O(x^{2/(r+1)} + \epsilon) \text{ where}$$

$$v_{r,s} = \sum_{k=0}^s (-1)^k g(k) \quad p > \prod_{(s+1)}^{1/r} \left(1 - \frac{k+2}{p^r}\right)$$

and

$$g(k) = g_{r,s}(k) = \sum_{1 \leq v_1 < \dots < v_s \leq s} \prod_{p \leq (s+1)}^{1/r} \left\{ 1 - \frac{D(p^r; 0, v_1, \dots, v_{r^{s+1}})}{p^k} \right\}$$

$$(v_{r,s} > 0) .$$

In particular, for fixed t the number of $q_i < x$ satisfying $q_{i+1} - q_i = t$ is known.

We remark also that K. Rogers [21] has shown that

$$\frac{Q(x)}{x} \geq \frac{53}{88}, \text{ with equality only at } x = 176, \quad (1.17)$$

that is, the Schuremann density of the square-free integers is less than their density, $\frac{6}{\pi^2}$.

3. The difference $Q(x) - \frac{6}{\pi^2} x$. Define $\mu_r(n)$ to be 0

or 1 according as n is or is not r -free, for $r = 2, 3, \dots$.

Then in particular $\mu_2(n) = |\mu(n)| = \mu^2(n)$. Define $Q_r(x)$ by

$$Q_r(x) = \sum_{n \leq x} \mu_r(n) .$$

In particular, $Q_2(x) = Q(x)$. Then, letting $[x]$ denote the greatest

integer $\leq x$, we have

$$\begin{aligned}
 Q_r(x) &= [x] - \left[\frac{x}{2^r} \right] - \left[\frac{x}{3^r} \right] - \left[\frac{x}{5^r} \right] - \left[\frac{x}{7^r} \right] - \dots + \left[\frac{x}{(2.3)^r} \right] + \left[\frac{x}{(2.5)^r} \right] + \\
 &\quad \dots - \left[\frac{x}{(2.3.5)^r} \right] - \dots \\
 &= \sum_{d^r \leq x} \mu(d) \left[\frac{x}{d^r} \right]. \tag{1.18}
 \end{aligned}$$

Alternately, since $\sum_{d^r | n} \mu(d) = \begin{cases} 1, & \text{if } n \text{ is } r\text{-free,} \\ 0 & \text{otherwise,} \end{cases}$

(for if $n = p_1^{\alpha_1} \dots p_k^{\alpha_k} n_1$, where $\alpha_i \geq r$ and n_1 is r -free, then the sum is $1 - \binom{k}{1} + \binom{k}{2} - \dots = (1-1)^k = 0$), we have

$$\sum_{d^r | n} \mu_r(d) = \mu_r(n).$$

Thus

$$\begin{aligned}
 Q_r(x) &= \sum_{n \leq x} \sum_{d^r | n} \mu(d) = \sum_{kd^r \leq x} \mu(d) = \sum_{d^r \leq x} \mu(d) \left(\sum_{\substack{n \leq x \\ d^r | n}} 1 \right) \\
 &= \sum_{d^r \leq x} \mu(d) \left[\frac{x}{d^r} \right]. \tag{1.19}
 \end{aligned}$$

Therefore,

$$|Q_r(x) - \frac{1}{\zeta(r)} x| \leq \left| \sum_{d^r \leq x} \mu(d) \left\{ \frac{x}{d^r} \right\} \right| + x \left| \sum_{d^r > x} \frac{\mu(d)}{d^r} \right|, \quad (1.20)$$

where $\{x\} = x - [x]$ is the fractional part of x . Hence, defining

$R_r(x)$ by $R_r(x) = Q_r(x) - \frac{1}{\zeta(r)} x$, we have

$$|R_r(x)| \leq x^{1/r} + \frac{1}{r-1} x^{1/r} + 1 = \frac{r}{r-1} x^{1/r} + 1, \quad (1.21)$$

since

$$\sum_{d^r > x} \frac{1}{d^r} < \frac{1}{x} + \int_{x^{1/r}}^{\infty} \frac{1}{u^r} = \frac{1}{x} + \frac{1}{r-1} \frac{x^{1/r}}{x}.$$

For $r = 2$, the best improvement in the constant 2 which appears in (1.21) was $\frac{12}{\pi}$ by Rogers [21]. Our main object in this chapter will be to obtain further improvements on this.

Let $M(x) = \sum_{n \leq x} \mu(n)$. R. D. von Sterneck [22] showed that

$$|M(x)| < \frac{1}{9} x + 8 \quad (1.22)$$

and R. Hackel [9] improved this to

$$|M(x)| < \frac{1}{26} x + 155, \quad \text{for all } x. \quad (1.23)$$

G. Neubauer [16] has shown that

$$|M(x)| < \frac{1}{2} \sqrt{x} , \quad \text{for } 200 < x \leq 10^8 . \quad (1.24)$$

Combining (1.23) and (1.24) we obtain

$$|M(x) + 2| < \frac{1}{25} x , \quad \text{for } x > 200 , \quad (1.25)$$

and one readily checks that (1.25) holds for $x \geq 100$. Thus, for

$x \geq 100^r$ and $r > 1$,

$$\begin{aligned} \left| \sum_{d^r > x} \frac{\mu(d)}{d^r} \right| &= \left| \sum_{d^r > x} (M(d) + 2) \left(\frac{1}{d^r} - \frac{1}{(d+1)^r} \right) - \frac{M(x^{1/r}) + 2}{([x^{1/r}] + 1)^r} \right| \\ &\leq \frac{1}{25} \sum_{d^r > x} d \left(\frac{1}{d^r} - \frac{1}{(d+1)^r} \right) + \frac{1}{25} \frac{x^{1/r}}{x} \\ &\leq \frac{1}{25} \left(\frac{x^{1/r}}{x} + \frac{1}{r-1} \frac{x^{1/r}}{x} + \frac{x^{1/r}}{x} \right) = \frac{1}{25} \left(2 + \frac{1}{r-1} \right) \frac{x^{1/r}}{x} . \end{aligned}$$

Therefore,

$$x \left| \sum_{d^r > x} \frac{\mu(d)}{d^r} \right| \leq \frac{1}{25} \left(2 + \frac{1}{r-1} \right) x^{1/r} , \quad \text{for } x \geq 100^r . \quad (1.26)$$

Let

$$A(x) = \sum_{\substack{d \leq x \\ \mu(\bar{d})=1}} 1 , \quad B(x) = \sum_{\substack{d \leq x \\ \mu(\bar{d})=-1}} 1 , \quad \text{and } C(x) = \max (A(x), B(x)) .$$

Then clearly

$$\left| \sum_{d \leq x} \mu(d) \{g(x, d)\} \right| \leq C(x) \quad \text{for any } g.$$

Now

$$C(x) = \frac{1}{2} (A(x) + B(x)) + \frac{1}{2} |A(x) - B(x)| = \frac{1}{2} Q(x) + \frac{1}{2} M(x).$$

Thus

$$\left| \sum_{d \leq x} \mu(d) \{g(x, d)\} \right| \leq \frac{1}{2} Q(x) + \frac{1}{2} M(x), \quad (1.27)$$

whence

$$\left| \sum_{d^r \leq x} \mu(d) \left\{ \frac{x}{d^r} \right\} \right| \leq \frac{13}{25} x^{1/r} + 1, \quad (1.28)$$

and

$$|R_r(x)| \leq \frac{16}{25} x^{1/r} + 1, \quad x \geq 100^r, \quad (1.29)$$

by (1.28) and (1.26). In particular,

$$\begin{aligned} Q(x) - \frac{6}{\pi^2} x &\leq \frac{16}{25} x^{1/2} + 1 \\ &\leq 0.65 x^{1/2}, \quad \text{for } x \geq 100^2. \end{aligned}$$

Using this in (1.27) we obtain

$$C(x) \leq \left(\frac{3}{\pi^2} + \frac{1}{50} \right) x + 0.325 x^{1/2}, \quad \text{for } x \geq 100^2.$$

Hence,

$$\left| \sum_{d^r \leq x} \mu(d) \left\{ \frac{x}{d^r} \right\} \right| < \frac{1}{3} x^{1/r} + 0.325 x^{1/2r}, \quad \text{for } x \geq 100^r \quad (1.30)$$

and

$$|R_r(x)| \leq \frac{28}{75} x^{1/r} + 0.325 x^{1/2r}, \quad \text{for } x \geq 100^r. \quad (1.31)$$

For $r = 2$, using (1.31) and examining the early cases, we find that

$$|R_2(x)| \leq \sqrt{3} \left(1 - \frac{6}{\pi^2} \right) x^{1/2} \quad \text{for all } x, \quad (1.32)$$

with equality only at $x = 3$ ($\sqrt{3}(1 - \frac{6}{\pi^2}) = 0.679 \dots$), and that

$$|R_2(x)| < \frac{1}{2} x^{1/2} \quad \text{for } x \geq 8. \quad (1.33)$$

The first place where $R_2(x)$ becomes negative is at $x = 28$. A. M. Vaidya [29] apparently has shown (the details have not yet been published) that $R_2(x)$ changes sign infinitely often, and that in fact for every $\epsilon > 0$ and infinitely many n , $R_2(n) > n^{1/4} - \epsilon$, and for infinitely many n , $R_2(n) < -n^{1/4} - \epsilon$; from this it follows that, for infinitely many n , $Q(n) = [\frac{6}{\pi^2} n + 1]$.

We have seen that

$$R_2(x) = O(x^{1/2}). \quad (1.34)$$

It is well known that $M(x) = O\left(\frac{x}{\log^\alpha x}\right)$ for arbitrary α (see e.g. E. Landau [11], p. 57). One can readily show from this that

$$R_2(x) = o\left(\frac{x^{1/2}}{\log^\alpha x}\right) \quad \text{for arbitrary } \alpha. \quad (1.35)$$

In the opposite direction, C. J. A. Evelyn and E. H. Linfoot [7] have shown that

$$R_2(x) \neq o(x^{1/4}). \quad (1.36)$$

CHAPTER 2

$$\text{On the Sum } M(x) = \sum_{n \leq x} \mu(n)$$

1. Introduction. Our object here will be to obtain the result

$$|M(x)| < \frac{x}{80} \quad \text{for } x \geq 1114, \quad (2.1)$$

an improvement of the results already cited of von Sterneck [27] and Hackel [9]. We first observe that, from Neubauer's [16] result that

$$|M(x)| < \frac{1}{2} \sqrt{x} \quad \text{for } 200 < x \leq 10^8, \quad (2.2)$$

we can prove (2.1) for $1114 \leq x \leq 10^8$. For since $\frac{1}{2} \sqrt{x} < \frac{x}{80}$ for $x > 1600$, (2.1) follows for $1600 < x \leq 10^8$, and one obtains by simple checking that (2.1) also holds for $1114 \leq x \leq 1600$; thus, (2.1) remains to be verified for $x > 10^8$.

2. The method. We outline the method to be used, which is a refinement of that of von Sterneck. Consider the function

$$f(x) = [x] - \left[\frac{x}{2}\right] - \left[\frac{x}{3}\right] - \left[\frac{x}{5}\right] + \left[\frac{x}{30}\right].$$

Since

$$\sum_{d \leq x} \mu(d) \left[\frac{x}{d} \right] = 1 ,$$

we have

$$\begin{aligned} \sum_{d \leq x} \mu(d) \left[\frac{x}{md} \right] &= \sum_{d \leq \frac{x}{m}} \mu(d) \left[\frac{x}{md} \right] + \sum_{\frac{x}{m} < d \leq x} \mu(d) \left[\frac{x}{md} \right] \\ &= 1 + 0 = 1 , \quad \text{for } x \geq m , \end{aligned}$$

and thus

$$\sum_{d \leq x} \mu(d) f\left(\frac{x}{d}\right) = -1 , \quad \text{for } x \geq 30 .$$

Since $f(x) = 1$ for $1 \leq x < 6$ and 0 or 1 for $x \geq 6$, we have $f\left(\frac{x}{d}\right) = 1$ for $d > \frac{x}{6}$, so that

$$\left| \sum_{d \leq x} \mu(d) (1 - f\left(\frac{x}{d}\right)) \right| \leq \sum_{d \leq \frac{x}{6}} |\mu(d)| = Q\left(\frac{x}{6}\right) .$$

Thus,

$$|M(x) + 1| \leq Q\left(\frac{x}{6}\right) , \quad \text{for } x \geq 30 . \quad (2.3)$$

We have from Chapter 1 that

$$\left| Q(x) - \frac{6}{\pi^2} x \right| < \frac{1}{2} \sqrt{x} , \quad \text{for } x \geq 8 . \quad (2.4)$$

It follows that

$$0.600x < Q(x) < 0.615x \quad \text{for } x \geq 5000 , \quad (2.5)$$

and one readily checks that (2.5) holds for $x \geq 475$. Similarly,

$$Q(x) < 0.635x \quad \text{for } x \geq 75 . \quad (2.6)$$

Using (2.5) in (2.3) we obtain

$$|M(x) + 1| \leq 0.103x \quad \text{for } x \geq 2950 \quad (2.7)$$

and, by (2.2), for $x > 200$. If we further observe that $f(x) = 1$ for $7 \leq x < 10$, we have

$$\begin{aligned} |M(x) + 1| &\leq Q\left(\frac{x}{6}\right) - Q\left(\frac{x}{7}\right) + Q\left(\frac{x}{10}\right) \\ &< 0.079x , \quad \text{for } x > 200 . \end{aligned} \quad (2.8)$$

Using the function

$$f_1(x) = [x] - \left[\frac{x}{2}\right] - \left[\frac{x}{3}\right] - \left[\frac{x}{5}\right] + \left[\frac{x}{15}\right] - \left[\frac{x}{30}\right]$$

and similar refinements to that used in deriving (2.8), one can obtain

$$|M(x) + 2| < 0.04x , \quad \text{for } x > 200 , \quad (2.9)$$

which is the same as (1.25). It seems difficult to get a fairly simple function like $f_1(x)$ which will substantially improve (2.9).

If we examine the characteristics of a 'good' function f , we see that what we would like is a function which takes the value 1 for $1 \leq x \leq n$ for fairly large n , and then does not differ too widely from 1 thereafter. We shall employ the techniques of E. Waage ([30] and [31]) to obtain such a function.

3. Main result. In line with Waage, we define

$$u_k(x) = \left[\frac{x}{k} \right] - \left[\frac{x}{k+1} \right] - \left[\frac{x}{k(k+1)} \right]$$

and use the symbol

$$(n_1, n_2, \dots, n_m; l_1, l_2, \dots, l_t)$$

to stand for the function

$$\left[\frac{x}{n_1} \right] + \left[\frac{x}{n_2} \right] + \dots + \left[\frac{x}{n_m} \right] - \left[\frac{x}{l_1} \right] - \left[\frac{x}{l_2} \right] - \dots - \left[\frac{x}{l_t} \right] .$$

Let

$$U_2(x) = u_1(x) = (1; 2, 2) ,$$

$$U_5(x) = u_1(x) + u_2(x) = (1; 2, 3, 6) ,$$

$$U_6(x) = U_5(x) - u_5(x) = (1, 30; 2, 3, 5) \quad (\text{this is our } f(x)) ,$$

$$U_{10}(x) = U_6(x) + u_6(x) = (1, 6, 30; 2, 3, 5, 7, 42) .$$

Define $U_s(x)$, $U_f(x)$, $u(x)$, and $u'(x)$, respectively, as follows:

$$\begin{aligned} U_s(x) &= U_{10}(x) - u_5\left(\frac{x}{6}\right) - u_6\left(\frac{x}{6}\right) + u_2\left(\frac{x}{35}\right) - u_1\left(\frac{x}{105}\right) - u_6\left(\frac{x}{30}\right) - u_5\left(\frac{x}{42}\right) \\ &= (1, 6, 70; 2, 3, 5, 7, 210) , \end{aligned}$$

$$\begin{aligned} U_f(x) &= U_s(x) + u_{10}(x) - u_2\left(\frac{x}{35}\right) - u_{21}\left(\frac{x}{5}\right) \\ &= (1, 6, 10, 2310; 2, 3, 5, 7, 11) , \end{aligned}$$

$$\begin{aligned}
 u(x) &= u_s(x) + u_1\left(\frac{x}{10}\right) + u_2\left(\frac{x}{10}\right) + u_1\left(\frac{x}{30}\right) + u_1\left(\frac{x}{14}\right) + 2u_1\left(\frac{x}{28}\right) \\
 &+ 4u_4\left(\frac{x}{14}\right) - u_1\left(\frac{x}{70}\right) - 2u_1\left(\frac{x}{140}\right) + u_1\left(\frac{x}{21}\right) + u_1\left(\frac{x}{35}\right) + u_2\left(\frac{x}{35}\right) \\
 &= (1, 6, 10, 14, 21, 35; 2, 3, 5, 7, 30, 30, 30, 42, 42, 70, 70, 70, 70, 105, 210, 210), \\
 u'(x) &= u_2\left(\frac{x}{5}\right) + u_6\left(\frac{x}{5}\right) - u_{14}(x) = (10; 14, 35) .
 \end{aligned}$$

Let R_1, R_2, R_3 , and R_4 be respectively the sets

$$\begin{aligned}
 &\{11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47\}, \{18, 70, 90, 90, 118, 134, 142, 146, 162, 177, 183, 213\} , \\
 &\{113, 131, 139, 154, 170, 173, 191\}, \{18, 18, 54, 90, 90, 105, 107, 108, 109, 700, 700, 700, 700\} ,
 \end{aligned}$$

Then the function $e(x)$ which we shall use is defined by the formula

$$\begin{aligned}
 e(x) &= u(x) - \sum_{r \in R_1} u_f\left(\frac{x}{r}\right) + u'\left(\frac{x}{7}\right) + 2u'\left(\frac{x}{14}\right) + u'\left(\frac{x}{17}\right) + u_5\left(\frac{x}{42}\right) - u_5\left(\frac{x}{79}\right) \\
 &- u_5\left(\frac{x}{101}\right) - u_5\left(\frac{x}{103}\right) - u_5\left(\frac{x}{137}\right) - u_5\left(\frac{x}{163}\right) - u_5\left(\frac{x}{167}\right) + 2u_6\left(\frac{x}{30}\right) + \sum_{r \in R_2} u_1\left(\frac{x}{r}\right) \\
 &- \sum_{r \in R_3} u_1\left(\frac{x}{r}\right) + \sum_{r \in R_4} u_2\left(\frac{x}{r}\right) - 2u_2\left(\frac{x}{1400}\right) + u_3\left(\frac{x}{18}\right) - u_3\left(\frac{x}{80}\right) + u_3\left(\frac{x}{108}\right) + 3u_4\left(\frac{x}{108}\right) \\
 &+ u_5\left(\frac{x}{3}\right) - 3u_8\left(\frac{x}{200}\right) + 6u_9\left(\frac{x}{60}\right) - 3u_9\left(\frac{x}{115}\right) + u_{10}\left(\frac{x}{21}\right) - 3u_{10}\left(\frac{x}{46}\right) + 3u_{10}\left(\frac{x}{92}\right) \\
 &- 3u_{10}\left(\frac{x}{103}\right) - 2u_{14}\left(\frac{x}{20}\right) + u_{18}\left(\frac{x}{18}\right) - 2u_{19}\left(\frac{x}{23}\right) + u_{21}\left(\frac{x}{14}\right) - 2u_{23}\left(\frac{x}{10}\right) - u_{26}\left(\frac{x}{12}\right) \\
 &+ u_{27}\left(\frac{x}{11}\right) + 3u_{33}\left(\frac{x}{10}\right) - u_{34}\left(\frac{x}{2}\right) + u_{44}\left(\frac{x}{5}\right) - 2u_{48}\left(\frac{x}{5}\right) + u_{49}\left(\frac{x}{8}\right) + u_{50}\left(\frac{x}{5}\right) -
 \end{aligned}$$

$$\begin{aligned}
 &= u_{50}\left(\frac{x}{10}\right) - u_{52}\left(\frac{x}{10}\right) - u_{53}(x) - 2u_{58}\left(\frac{x}{100}\right) - u_{59}(x) + u_{60}(x) + 3u_{60}\left(\frac{x}{10}\right) \\
 &= u_{67}(x) + 3u_{67}\left(\frac{x}{100}\right) + u_{68}\left(\frac{x}{5}\right) - u_{68}\left(\frac{x}{10}\right) + u_{70}(x) + u_{72}(x) - u_{81}\left(\frac{x}{20}\right) \\
 &= u_{83}(x) - u_{89}(x) + u_{90}\left(\frac{x}{2}\right) + u_{94}\left(\frac{x}{10}\right) - u_{96}\left(\frac{x}{3}\right) - u_{97}(x) + u_{106}(x) \\
 &+ u_{108}(x) + 2u_{109}\left(\frac{x}{3}\right) - u_{114}\left(\frac{x}{2}\right) - u_{121}(x) + u_{126}(x) - u_{139}\left(\frac{x}{2}\right) - u_{143}\left(\frac{x}{2}\right) \\
 &= u_{144}\left(\frac{x}{20}\right) - u_{149}(x) + u_{150}(x) - u_{157}(x) - u_{158}(x) - u_{165}(x) + u_{178}(x) \\
 &+ u_{180}(x) - u_{193}(x) - u_{195}(x) + u_{196}(x) - u_{199}(x) - u_{200}(x) + u_{210}(x) \\
 &= u_{263}(x) - u_{264}(x) + u_{264}\left(\frac{x}{10}\right) - u_{266}(x) + u_{270}(x) + 3u_{270}\left(\frac{x}{20}\right) - u_{283}(x) \\
 &= u_{320}(x) \\
 &= \sum_{n=1}^{218} \mu(n) \left[\frac{x}{n}\right] + \sum_{p \in P} \left[\frac{x}{p}\right] - \sum_{q \in Q} \left[\frac{x}{q}\right] ,
 \end{aligned}$$

where

$$\begin{aligned}
 P = \{ &220, 226, 226, 235, 237, 245, 250, 253, 259, 262, 262, 265, 267, 274, 278, \\

 $699600, 1463400, 1463400, 1463400\}.$

This rather complicated function was obtained by successively evaluating simpler functions by computer to see where they began to differ too much from 1, and adding in compensating simple functions to reduce the rate of growth.

Since there are 222 positive terms and 226 negative terms in g ,

$$|e(x)| \leq 226 \quad \text{for all } x, \quad (2.11)$$

for when we remove the square brackets in e the function is identically zero by construction. Upon examining $e(x)$, we find that

$$e(x) = 1, \quad \text{for } 1 \leq x < 219 \quad (2.12)$$

and

$$|e(x)-1| \leq k \quad \text{for } x < n, \quad (2.13)$$

where k and n are as given in the following table:

k	1	2	3	4	5	6	7	8	9	10	11
n	345	568	584	804	1237	1359	1391	1393	1416	1416	1417

k	12	13	14	15	16	17	18	19	20
n	5010	5011	5881	5882	16097	16100	16100	16103	26740

k	21	22	23	24	25	26	27	28	29
n	26750	26752	26754	26759	31397	46110	46110	46112	63611

k	30	31	32	33	34	35	36	37	38
n	67158	67159	67189	69258	69259	69263	82800	82800	82813

k	39	40	41	42	43	44	45
n	85869	87542	87547	97006	97007	106591	up to 125000

Let N be the set of n 's in the above table. It follows that

$$|M(x) + 4| \leq Q\left(\frac{x}{219}\right) + \sum_{n \in N} Q\left(\frac{x}{n}\right) + (226 - 45) Q\left(\frac{x}{12500}\right) . \quad (2.14)$$

Using (2.4) and (2.5) in (2.14) we obtain

$$|M(x) + 4| \leq 0.01247 x , \quad \text{for } x > 10^8$$

or

$$|M(x)| < \frac{1}{80} x , \quad \text{for } x > 10^8 .$$

This completes the proof of (2.1).

It is likely that with a better function $e(x)$ one could prove

$$|M(x)| < .01 x , \quad \text{for } x \geq 1137 .$$

This is certainly true for $1137 \leq x \leq 10^8$.

4. Application. S. Selberg [25] has shown that, if $g(x)$ is defined by

$$g(x) = \sum_{n \leq x} \frac{\mu(n)}{n} ,$$

Let $f: \mathbb{R} \rightarrow \mathbb{R}$ be a function such that $f(x) = x^2 \sin\left(\frac{1}{x}\right)$ for $x \neq 0$ and $f(0) = 0$.

Prove that f is differentiable at $x = 0$ and find $f'(0)$.

Using the definition of the derivative, show that $f'(0) = 0$.

What is the value of $f'(0)$?

Is f differentiable at $x = 0$?

Find $f'(x)$ for $x \neq 0$.

What is the value of $f'(x)$ for $x \neq 0$?

Does f have a unique tangent line at $x = 0$?

What is the value of $f'(x)$ for $x \neq 0$?

What is the value of $f'(x)$ for $x \neq 0$?

What is the value of $f'(x)$ for $x \neq 0$?

then $g(x)$ changes sign infinitely often. We show here that, on the other hand, $g_1(x)$, defined by

$$g_1(x) = \sum_{14 \leq n \leq x} \frac{\mu(n)}{n} = g(x) - \sum_{n \leq 13} \frac{\mu(n)}{n},$$

is always positive, or, what is the same thing, that $g(x)$ has its minimum at $x = 13$.

We note that

$$\sum_{n=1}^{\infty} \frac{\mu(n)}{n} = 0 \quad (2.15)$$

(see e.g. Landau [11], page 159) and observe that

$$\sum_{n \leq 13} \frac{\mu(n)}{n} = -0.0773559 \dots \quad (2.16)$$

To show that

$$\left| \sum_{n \leq x} \frac{\mu(n)}{n} \right| < 0.07 \quad \text{for } 200 < x \leq 10^8$$

we can use $|M(x)| < \frac{1}{2} \sqrt{x}$. Then, for $900 \leq x < 10^8$ we have

$$\sum_{d \leq x} \frac{\mu(d)}{d} = \sum_{d \leq 900} \frac{\mu(d)}{d} + \sum_{900 < d \leq x-1} \frac{M(d)}{d(d+1)} - \frac{M(900)}{901} + \frac{M(x)}{x}.$$

Since

$$\sum_{d \leq 900} \frac{\mu(d)}{d} = 0.00328 \dots \text{ and } M(900) = 1$$

we obtain

$$\begin{aligned} \left| \sum_{d \leq x} \frac{\mu(d)}{d} \right| &= 0.00217 \dots + \frac{1}{2} \sum_{900 < d \leq x-1} \frac{1}{d^{3/2}} + \frac{1}{2} \frac{1}{x^{1/2}} \\ &< 0.036, \quad \text{for } 900 \leq x \leq 10^8. \end{aligned} \quad (2.17)$$

One readily checks $g(x)$ for $1 \leq x \leq 900$, and we have that, for $1 \leq x \leq 10^8$, g assumes its minimum only at $x = 13$. So it remains only to check for $x > 10^8$.

Since

$$\sum_{d \leq x} \mu(d) \left[\frac{x}{d} \right] = 1,$$

we have

$$\sum_{d \leq x} \frac{\mu(d)}{d} = \frac{1}{x} + \frac{1}{x} \sum_{d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}. \quad (2.18)$$

Now,

$$\begin{aligned}
 \sum_{d \leq x} \mu(d) \left\{ \frac{x}{d} \right\} &= \sum_{\frac{x}{2} < d \leq x} \mu(d) \left(\frac{x}{d} - 1 \right) + \sum_{\frac{x}{3} < d \leq \frac{x}{2}} \mu(d) \left(\frac{x}{d} - 2 \right) + \dots + \sum_{\frac{x}{k} < d \leq \frac{x}{k-1}} \mu(d) \left(\frac{x}{d} - (k-1) \right) \\
 &\quad + \sum_{d \leq \frac{x}{k}} \mu(d) \left\{ \frac{x}{d} \right\} \\
 &= x \sum_{\frac{x}{k} < d \leq x} \frac{\mu(d)}{d} - \sum_{1 \leq t \leq k-1} M\left(\frac{x}{t}\right) + (k-1)M\left(\frac{x}{k}\right) + \sum_{d \leq \frac{x}{k}} \mu(d) \left\{ \frac{x}{d} \right\} .
 \end{aligned}$$

Therefore, using (2.18), it follows that

$$\sum_{d \leq \frac{x}{k}} \frac{\mu(d)}{d} = \frac{1}{x} - \frac{1}{x} \sum_{1 \leq t \leq k-1} M\left(\frac{x}{t}\right) + \frac{k-1}{x} M\left(\frac{x}{k}\right) + \frac{1}{x} \sum_{d \leq \frac{x}{k}} \mu(d) \left\{ \frac{x}{d} \right\} , \quad x \geq k .$$

Hence,

$$\sum_{d \leq x} \frac{\mu(d)}{d} = \frac{1}{kx} - \frac{1}{kx} \sum_{1 \leq t \leq k-1} M\left(k \frac{x}{t}\right) + \frac{k-1}{kx} M(x) + \frac{1}{kx} \sum_{d \leq x} \mu(d) \left\{ \frac{kx}{d} \right\}, \quad \text{for } x \geq 1 . \quad (2.19)$$

Using (2.1) in (2.19), we obtain

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d} \right| \leq \frac{1}{kx} + \frac{1}{80} \sum_{1 \leq t \leq k-1} \frac{1}{t} + \frac{1}{80} \frac{k-1}{k} + \frac{1}{kx} \left| \sum_{d \leq x} \mu(d) \left\{ \frac{kx}{d} \right\} \right| .$$

From (1.27), using (2.4), we have

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d} \right| \leq \frac{1}{kx} + \frac{1}{80} \sum_{1 \leq t \leq k-1} \frac{1}{t} + \frac{1}{80} \frac{k-1}{k} + \frac{0.305}{k} + \frac{1}{160k} , \quad \text{for } x > 60,000 .$$

Choosing k to be 20 , we have

$$\left| \sum_{\underline{d} \leq x} \frac{\mu(d)}{d} \right| \leq 0.073 , \quad \text{for } x > 60,000. \quad (2.20)$$

This suffices to complete the proof.

We have shown that, if

$$g(x) = \sum_{\underline{n} \leq x} \frac{\mu(n)}{n} ,$$

then $g(x)$ assumes its minimum at $x = 13$. If we define $g_r(x)$ by

$$g_r(x) = \sum_{\underline{n} \leq x} \frac{\mu(n)}{n^r} ,$$

then it is rather easy to show that, at least for integer $r \geq 2$,

$g_r(x)$ assumes its minimum at $x = 5$. For

$$\sum_{\underline{n} \leq x} \frac{\mu(n)}{n^r} = 1 - \frac{1}{2^r} - \frac{1}{3^r} - \frac{1}{5^r} + \frac{1}{6^r} - \frac{1}{7^r} + \frac{1}{10^r} - \frac{1}{11^r} - \frac{1}{13^r} + \frac{1}{14^r} + \dots .$$

It is easy to see that the minimum cannot occur for $5 < x < 13$. For

$r \geq 4$, we shall show that

$$\frac{1}{6^r} + \frac{1}{10^r} > \frac{1}{7^r} + \sum_{d=11}^{\infty} \frac{1}{d^r} , \quad (2.21)$$

so that the sum beyond $x = 5$ is always positive, and hence the minimum

occurs at $x = 5$.

Since

$$\sum_{d=11}^{\infty} \frac{1}{d^r} < \int_{10}^{\infty} \frac{1}{u^r} du = \frac{10}{r-1} \frac{1}{10^r} ,$$

we have

$$\begin{aligned} \frac{1}{7^r} - \frac{1}{10^r} + \sum_{d=11}^{\infty} \frac{1}{d^r} &< \frac{11-r}{r-1} \frac{1}{10^r} + \frac{1}{7^r} \leq \frac{2^{\frac{1}{3}}}{10^r} + \frac{1}{7^r} \\ &= \frac{2^{\frac{1}{3}}}{7^r} \left(\frac{7}{10}\right)^r + \frac{1}{7^r} \leq \frac{2^{\frac{1}{3}}}{10^r} \left(\frac{7}{10}\right)^r + \frac{1}{7^r} \\ &< \frac{1.6}{7^r} = \frac{1.6}{6^r} \left(\frac{6}{7}\right)^r \leq \frac{1.6}{6^r} \left(\frac{6}{7}\right)^4 \\ &< \frac{1}{6^r} . \end{aligned}$$

So the minimum occurs at $x = 5$ for all $r \geq 4$ (not just integer r) .

One can use (2.1) to obtain

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d^r} - \frac{1}{\zeta(r)} \right| \leq \frac{1}{80} \left(2 + \frac{1}{r-1}\right) \frac{1}{x^{r-1}} , \quad \text{for } x \geq 694 \quad \text{and} \\ r > 1 . \quad (2.22)$$

Using this to examine $r = 2$ and $r = 3$ we again find that the minimum

occurs at $x = 5$. Indeed, it seems that there is an r_0 between 1

and 2 , namely the solution of $\frac{1}{6^r} + \frac{1}{10^r} = \frac{1}{7^r} + \frac{1}{11^r} + \frac{1}{13^r}$, such

that, for $1 \leq r < r_0$ the minimum occurs at $x = 13$, for r_0 there are twin minima at $x = 13$ and $x = 5$, and for $r > r_0$ the minimum occurs at $x = 5$.

CHAPTER 3

The Minimum of $\frac{\Phi(x)}{x^2}$

1. Introduction. Let $\varphi(n)$ denote Euler's function, so that

$$\varphi(n) = n \prod_{p|n} \left(1 - \frac{1}{p}\right) = n \sum_{d|n} \frac{\mu(d)}{d}.$$

Define

$$\Phi(x) \text{ by } \Phi(x) = \sum_{d \leq x} \varphi(d).$$

Then we have

$$\begin{aligned} \Phi(x) &= \sum_{d \leq x} d \sum_{k|d} \frac{\mu(k)}{k} = \sum_{d \leq x} \mu(d) \sum_{n \leq \frac{x}{d}} n \\ &= \frac{1}{2} \sum_{d \leq x} \mu(d) \left[\frac{x}{d} \right]^2 + \frac{1}{2} \\ &= \frac{1}{2} \sum_{d \leq x} \mu(d) \left(\frac{x^2}{d^2} - 2 \frac{x}{d} \left\{ \frac{x}{d} \right\} + \left\{ \frac{x}{d} \right\}^2 \right) + \frac{1}{2}. \end{aligned} \tag{3.1}$$

Hence,

$$\begin{aligned} \left| \Phi(x) - \frac{3}{\pi} x^2 \right| &\leq \frac{1}{2} x^2 \left| \sum_{d > x} \frac{\mu(d)}{d^2} \right| + x \left| \sum_{d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} \right| + \\ &+ \frac{1}{2} \left| \sum_{d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2 \right| + \frac{1}{2} . \end{aligned} \quad (3.2)$$

Using the trivial estimates

$$\left| \sum_{d > x} \frac{\mu(d)}{d^2} \right| \leq \frac{1}{[x]} \leq \frac{1}{x} + \frac{2}{x^2} ,$$

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} \right| \leq \log x + 1 ,$$

and

$$\left| \sum_{d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2 \right| \leq x ,$$

we have

$$\left| \Phi(x) - \frac{3}{\pi} x^2 \right| \leq x \log x + 2x + \frac{3}{2} . \quad (3.3)$$

In particular, if $R(x) = \Phi(x) - \frac{3}{\pi} x^2$, then

$$R(x) = O(x \log x) . \quad (3.4)$$

Equation (3.4) was first proved by F. Mertens [13] in 1874, and even minor improvement seems hard to come by. In a long and difficult paper A. Walfisz [32] in 1953 showed that

$$R(x) = O(x (\log x)^{3/4} (\log \log x)^2) , \quad (3.5)$$

and A. Saltykov [23] in 1960 replaced $3/4$ by $2/3$ and 2 by $(1+\epsilon)$. In the opposite direction S. S. Pillai and S. D. Chowla [18] showed that

$$R(x) \neq o(x \log \log \log x) , \quad (3.6)$$

and also that

$$\sum_{n \leq x} R(n) = \frac{3}{2\pi^2} x^2 + o(x^2) . \quad (3.7)$$

J. J. Sylvester [28] conjectured that $R(x) > 0$, for all positive integers x , a result which holds for small x . But M. L. N. Sarma [24] showed that $R(820) < 0$, while P. Erdos and H. N. Shapiro [5] showed that $R(x)$ changes sign for infinitely many integers x , and indeed that there exists a positive constant c and infinitely many integers x such that

$$R(x) > cx \log \log \log \log x$$

and infinitely many integers x such that

$$R(x) < -cx \log \log \log \log x .$$

We consider here the problem of determining the S-density of $\Phi(x)$, that is, of finding

$$S(\Phi) = \min_{\text{integer } x > 0} \frac{\Phi(x)}{x^2} - \frac{3}{\pi^2} = \min_{\text{integer } x > 0} \frac{R(x)}{x^2}. \quad (3.8)$$

We show that this minimum occurs at $x = 1276$ (1276 is the second integer x for which $R(x) < 0$), where $\frac{R(x)}{x^2}$ has the value $\frac{274,433}{814,088} - \frac{3}{\pi^2} = -0.2466 \dots \times 10^{-4}$; this is done by showing that,

$$\left| \frac{\Phi(x)}{x^2} - \frac{3}{\pi^2} \right| < \left| \frac{\Phi(1276)}{(1276)^2} - \frac{3}{\pi^2} \right|, \quad \text{for } x > 150,000, \quad (3.9)$$

and then using the computer to check the remaining values of x .

2. Proof of (3.9) In what follows, let x be an integer.

(Note: If we dropped this requirement on x , the result (3.9) would often not hold for values of x just below smaller integers. However, if instead of the step function

$$\Phi(x) = \sum_{n \leq x} \varphi(n)$$

we worked with the continuous function

$$\Phi_1(x) = \sum_{n \leq x} \varphi(n) + \{x\} \varphi([x+1]),$$

(3.9) would hold for all $x \neq 1276$ by fairly straight forward extensions of the work herein.)

From (3.3), we have

$$\left| \frac{\phi(x)}{x^2} - \frac{3}{\pi^2} \right| \leq \frac{2}{x} + \frac{\log x}{x} + \frac{3}{2x^2} < 0.24 \times 10^{-4} \quad \text{for } x > 650,000. \quad (3.10)$$

We could ask the computer to check up to 650,000, but the time required increases very rapidly with x , so to save computer time we shall reduce this to 150,000 by improving the trivial result (3.3).

We have

$$\sum_{d > x} \frac{\mu(d)}{d^2} = \sum_{d > x} M(d) \left(\frac{1}{d^2} - \frac{1}{(d+1)^2} \right) - \frac{M(x)}{(x+1)^2}$$

so that, using (2.1),

$$\begin{aligned} \left| \sum_{d > x} \frac{\mu(d)}{d^2} \right| &\leq \frac{1}{80} \sum_{d > x} d \left(\frac{1}{d^2} - \frac{1}{(d+1)^2} \right) + \frac{1}{80} \frac{1}{x} \\ &\leq \frac{1}{40} \frac{1}{x} + \frac{1}{80} \frac{1}{x} = \frac{3}{80} \frac{1}{x}, \quad \text{for } x \geq 1114. \quad (3.11) \end{aligned}$$

Let

$$\sum_{d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2 = \sum_{d \leq \frac{x}{k}} \mu(d) \left\{ \frac{x}{d} \right\}^2 + \sum_{\frac{x}{k} \leq d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2,$$

where k will be an appropriately chosen integer. From (3.5) we have

$$\left| \sum_{d \leq \frac{x}{k}} \mu(d) \left\{ \frac{x}{d} \right\}^2 \right| \leq \sum_{d \leq \frac{x}{k}} |\mu(d)| = Q\left(\frac{x}{k}\right) < 0.615 \frac{x}{k}, \quad \text{for } x \geq 475 k. \quad (3.12)$$

Also,

$$\begin{aligned} \sum_{\frac{x}{k} < d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2 &= \sum_{\frac{x}{k} < d \leq x-1} \mu(d) \left(\left\{ \frac{x}{d} \right\} - \left\{ \frac{x}{d+1} \right\} \right) \left(\left\{ \frac{x}{d} \right\} + \left\{ \frac{x}{d+1} \right\} \right) \\ &= M\left(\frac{x}{k}\right) \left\{ \frac{x}{\left[\frac{x}{k} \right] + 1} \right\}^2. \end{aligned}$$

Now, for $\frac{x}{k} < d$, we have $\left[\frac{x}{d} \right] \leq k-1$, so that $\left[\frac{x}{d} \right] \neq \left[\frac{x}{d+1} \right]$, for at most k values of d , or, equivalently, $\left\{ \frac{x}{d} \right\} - \left\{ \frac{x}{d+1} \right\} = \frac{x}{d(d+1)}$ with at most k exceptions. Also, $\left| \left\{ \frac{x}{d} \right\} + \left\{ \frac{x}{d+1} \right\} \right| < 2$, and for $\frac{x}{k} < d \leq x-1$ we can use the result that $|M(d)| < \frac{1}{2} \sqrt{d}$ for $\frac{x}{d} \geq 200$ and $x \leq 10^8$, i.e. for $200 k \leq x \leq 10^8$. As our k will be 25, this gives

$$|M(d)| < \frac{1}{2} \sqrt{d}, \quad \text{for } 5000 \leq x \leq 10^8.$$

Thus, we have

$$\begin{aligned}
 \left| \sum_{\frac{x}{k} < d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2 \right| &\leq 2x \sum_{\frac{x}{k} < d \leq x-1} \frac{|M(d)|}{d(d+1)} + k \cdot \frac{1}{2} \sqrt{x} + \left| M\left(\frac{x}{k}\right) \right| \\
 &< x \sum_{\frac{x}{k} < d \leq x-1} \frac{1}{\sqrt{d} (d+1)} + \frac{1}{2} k \sqrt{x} + \frac{1}{2\sqrt{k}} \sqrt{x} \\
 &\leq 2x \frac{\sqrt{k} - 1}{\sqrt{x}} + \frac{1}{2} k \sqrt{x} + \frac{1}{2\sqrt{k}} \sqrt{x} \\
 &= \sqrt{x} \left(\frac{k}{2} + 2\sqrt{k} - 2 + \frac{1}{2\sqrt{k}} \right), \quad \text{for } 5000 \leq x \leq 10^8. \quad (3.13)
 \end{aligned}$$

Therefore,

$$\begin{aligned}
 \left| \sum_{d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2 \right| &< 0.615 \frac{x}{k} + \sqrt{x} \left(\frac{k}{2} + 2\sqrt{k} - 2 + \frac{1}{2\sqrt{k}} \right) \\
 &\quad \text{for } 5000 \leq x \leq 10^8 \quad \text{and } x \geq 475 k.
 \end{aligned}$$

When $k = 25$, the right hand side becomes $0.0246 x + 20.6 \sqrt{x}$, and

$$\left| \sum_{d \leq x} \mu(d) \left\{ \frac{x}{d} \right\}^2 \right| < 0.078 x, \quad \text{for } 150,000 \leq x \leq 10^8. \quad (3.14)$$

We now consider the sum

$$\sum_{d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\}.$$

Writing

$$A_1(x) = \sum_{\substack{d \leq x \\ \mu(d)=1}} \frac{1}{d}, \quad B_1(x) = \sum_{\substack{d \leq x \\ \mu(d)=-1}} \frac{1}{d}, \quad \text{and} \quad C_1(x) = \max(A_1(x), B_1(x)),$$

we see that

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} \right| \leq C_1(x). \quad (3.15)$$

Now, $C_1(x) = \frac{1}{2} (A_1(x) + B_1(x) + |A_1(x) - B_1(x)|)$, so that

$$C_1(x) = \frac{1}{2} \sum_{d \leq x} \frac{|\mu(d)|}{d} + \frac{1}{2} \left| \sum_{d \leq x} \frac{\mu(d)}{d} \right|. \quad (3.16)$$

From (2.15) we had

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d} \right| < 0.036 \quad \text{for} \quad 900 \leq x \leq 10^8.$$

For $x \geq 900$ we have

$$\sum_{d \leq x} \frac{|\mu(d)|}{d} = \sum_{d \leq 900} \frac{|\mu(d)|}{d} + \sum_{900 < d \leq x-1} \frac{Q(d)}{d(d+1)} + \frac{Q(x)}{x} - \frac{Q(900)}{901}.$$

Using (2.5), and observing that

$$\sum_{d \leq 900} \frac{|\mu(d)|}{d} = 5.178 \dots \quad \text{and} \quad Q(900) = 547,$$

we have

$$\sum_{d \leq x} \frac{|\mu(d)|}{d} \leq 0.615 \log x + 1.012, \quad \text{for } x \geq 900. \quad (3.17)$$

Combining (2.15) and (3.17) in (3.16), we obtain

$$C_1(x) \leq 0.3075 \log x + 0.506, \quad \text{for } 900 \leq x \leq 10^8, \quad (3.18)$$

and

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} \right| \leq 0.3075 \log x + 0.506, \quad \text{for } 900 \leq x \leq 10^8. \quad (3.19)$$

Unfortunately, (3.19) is not quite strong enough to give us our required result, and we must proceed as follows: for $k = 25$, (3.18) yields

$$\begin{aligned} \left| \sum_{d \leq \frac{x}{k}} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} \right| &\leq 0.3075 \log \frac{x}{25} + 0.506 \\ &< 0.3075 \log x - 0.482, \quad \text{for } 22500 \leq x \leq 10^8. \end{aligned} \quad (3.20)$$

On the other hand,

$$\sum_{\frac{x}{k} < d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} = \sum_{\frac{x}{k} < d \leq x-1} M(d) \left(\left\{ \frac{x}{d} \right\} / d - \left\{ \frac{x}{d+1} \right\} / (d+1) \right) - M\left(\frac{x}{k}\right) \frac{\left\{ \frac{x}{\left\lfloor \frac{x}{k} \right\rfloor + 1} \right\}}{\left\lfloor \frac{x}{k} \right\rfloor + 1}.$$

Now,

Let \mathcal{H} be a Hilbert space and \mathcal{H}^* its dual space. Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

$$\mathcal{H} \otimes \mathcal{H}^* = \bigoplus_{i=1}^{\infty} \mathcal{H}_i \otimes \mathcal{H}_i^*$$

Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

Let $\mathcal{H} \otimes \mathcal{H}^*$ be the tensor product of \mathcal{H} and \mathcal{H}^* .

$$\frac{1}{2} \left(\frac{1}{2} \right) = \frac{1}{4} \left(\frac{1}{2} \right) = \frac{1}{8} \left(\frac{1}{2} \right) = \frac{1}{16} \left(\frac{1}{2} \right) = \frac{1}{32} \left(\frac{1}{2} \right) = \frac{1}{64} \left(\frac{1}{2} \right) = \frac{1}{128} \left(\frac{1}{2} \right) = \frac{1}{256} \left(\frac{1}{2} \right) = \frac{1}{512} \left(\frac{1}{2} \right) = \frac{1}{1024} $$\left\{\frac{x}{d}\right\}/d - \left\{\frac{x}{d+1}\right\}/(d+1) = \left(\left\{\frac{x}{d}\right\} - \left\{\frac{x}{d+1}\right\}\right)/(d+1) + \left\{\frac{x}{d}\right\}/d(d+1) .$$

As above, we note that $\left\{\frac{x}{d}\right\} - \left\{\frac{x}{d+1}\right\} = \frac{x}{d(d+1)}$ except for at most k values of d . For these exceptional values

$$|M(d)\left(\left\{\frac{x}{d}\right\} - \left\{\frac{x}{d+1}\right\}\right)|/(d+1) < \frac{|M(d)|}{d+1} < \frac{1}{2} \frac{1}{\sqrt{x/k}} = \frac{\sqrt{k}}{2\sqrt{x}} ,$$

where we use the fact that $M(d) < \frac{1}{2} \sqrt{d}$ for $\frac{x}{25} > 200$ and $x \leq 10^8$, i.e. for $5000 \leq x \leq 10^8$. Thus,

$$\begin{aligned} \left| \sum_{\frac{x}{k} < d \leq x} \frac{\mu(d)}{d} \left\{\frac{x}{d}\right\} \right| &\leq x \sum_{\frac{x}{k} < d \leq x-1} \frac{|M(d)|}{d(d+1)^2} + \frac{k^{3/2}}{2\sqrt{x}} \\ &+ \sum_{\frac{x}{k} < d \leq x-1} \frac{|M(d)|}{d(d+1)} + |M(\frac{x}{k})|/\frac{x}{k} \\ &\leq \frac{1}{2} x \sum_{\frac{x}{k} < d \leq x-1} \frac{1}{\sqrt{d}(d+1)^2} + \frac{1}{2} \sum_{\frac{x}{k} < d \leq x-1} \frac{1}{\sqrt{d}(d+1)} \\ &+ \frac{k^{3/2}}{2\sqrt{x}} + \frac{\sqrt{k}}{2\sqrt{x}} \\ &\leq \frac{(k^{3/2} - 1)}{3\sqrt{x}} + \frac{(\sqrt{k} - 1)}{\sqrt{x}} + \frac{k^{3/2}}{2\sqrt{x}} + \frac{\sqrt{k}}{2\sqrt{x}} . \end{aligned}$$

Substituting $k = 25$, we get

$$\left| \sum_{\frac{x}{k} < d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} \right| \leq \frac{332}{3 \sqrt{x}}, \quad \text{for } 5000 < x \leq 10^8,$$

$$< 0.287, \quad \text{for } 150,000 \leq x \leq 10^8, \quad (3.21)$$

so that, with (3.20), we have

$$\left| \sum_{d \leq x} \frac{\mu(d)}{d} \left\{ \frac{x}{d} \right\} \right| \leq 0.3075 \log x - 0.195. \quad (3.22)$$

Hence, using (3.22), (3.14), and (3.11) in (3.2) we have

$$\left| \frac{\Phi(x)}{x^2} - \frac{3}{\pi^2} \right| \leq 0.3075 \frac{\log x}{x} - \frac{0.079}{x} + \frac{1}{2x^2}$$

$$< 0.24 x^{-4}, \quad \text{for } 150,000 \leq x \leq 10^8. \quad (3.23)$$

So now we have only to check for $x < 150,000$.

3. The computer work. Theorems 3.1 and 3.2 are essentially due to R. S. Lehman [11], who gave the results for $h(n) = \lambda(n) = (-1)^r$, where $n = p_1^{\alpha_1} \dots p_r^{\alpha_r}$.

Theorem 3.1. Let $H(x) = \sum_{n \leq x} h(n)$, $f(x) = \sum_{n \leq x} H\left(\frac{x}{n}\right)$. Then

$$H(x) = \sum_{m \leq x/w} \mu(m) \left\{ f\left(\frac{x}{m}\right) - \sum_{k < v} h(k) \left(\left[\frac{x}{km} \right] - \left[\frac{x}{vm} \right] \right) \right\} - \sum_{x/w < \ell \leq x/v} H\left(\frac{x}{\ell}\right) \sum_{\substack{m | \ell \\ m \leq x/w}} \mu(m),$$

$$(3.24)$$

where $1 < v < w < x$.

Proof.
$$f\left(\frac{x}{m}\right) = \sum_{n \leq x/mw} H\left(\frac{x}{mn}\right) + \sum_{x/mw < n \leq x/mv} H\left(\frac{x}{mn}\right) + \sum_{x/mv < n \leq x/m} H\left(\frac{x}{mn}\right).$$

Multiply each by $\mu(m)$, and sum for $m \leq \frac{x}{w}$.

$$1. \quad \sum_{m \leq x/w} \mu(m) \sum_{n \leq x/mw} H\left(\frac{x}{mn}\right) = \sum_{\ell \leq x/w} H\left(\frac{x}{\ell}\right) \sum_{m|\ell} \mu(m) = H(x).$$

$$2. \quad \sum_{m \leq x/w} \mu(m) \sum_{x/mw < n \leq x/mv} H\left(\frac{x}{mn}\right) = \sum_{x/w < \ell \leq x/v} H\left(\frac{x}{\ell}\right) \sum_{\substack{m|\ell \\ m \leq x/w}} \mu(m).$$

$$\begin{aligned} 3. \quad \sum_{m \leq x/w} \mu(m) \sum_{x/mv < n \leq x/m} H\left(\frac{x}{mn}\right) &= \sum_{m \leq x/w} \mu(m) \sum_{x/mv < n \leq x/m} \sum_{k \leq x/mn} h(k) \\ &= \sum_{m \leq x/w} \mu(m) \sum_{k < v} h(k) \sum_{x/mv < n \leq x/km} 1 \\ &= \sum_{m \leq x/w} \mu(m) \sum_{k < v} h(k) \left(\left[\frac{x}{km} \right] - \left[\frac{x}{vm} \right] \right). \end{aligned}$$

Rearrangement of terms then yields the theorem. We note that, by choosing $v \approx x^{1/3}$ and $w \approx x^{2/3}$, if we have tables of $\mu(m)$ and $h(m)$ for $m \leq v$, $H(m)$ for $m \leq w$, and $\xi(\ell) = \sum_{\substack{m|\ell \\ m \leq x/w}} \mu(m)$ for

$\ell \leq \frac{x}{v}$, then the number of operations is proportional to $x^{2/3}$. The last-mentioned tables can readily be computed as the program progresses by adding $\mu(\lfloor \frac{x}{w} \rfloor)$ to each $\lfloor \frac{x}{w} \rfloor$ -th value of ξ whenever $\lfloor \frac{x}{w} \rfloor$ increases by 1.

The following slightly more complicated formula is in practice more efficient, cutting the time by about one half.

Theorem 3.2. Let

$$f(x) = \sum_{n \leq x} H\left(\frac{x}{n}\right) \quad \text{and} \quad H(x) = \sum_{n \leq x} h(n) .$$

Let K' , L' , and M' range over positive odd integers, and I over positive integers. Then

$$\begin{aligned} H(N) &= \sum_{M' \leq N/w} \mu(M') \left\{ f\left(\frac{N}{M'}\right) - f\left(\frac{N}{2M'}\right) - \left(\sum_{I < v} h(I) \left(\frac{N+IM'}{2IM'} \right) - \frac{N+vM'}{2vM'} H(v-1) \right) \right\} \\ &= \sum_{N/w+1 \leq K' \leq N/v} H\left(\frac{N}{K'}\right) \sum_{\substack{L' | K' \\ L' \leq N/w}} \mu(L') , \quad \text{where } 1 < v < w < N . \quad (3.25) \end{aligned}$$

Proof. From $f(x) = \sum_{n \leq x} H\left(\frac{x}{n}\right)$ we get $f(x) - f\left(\frac{x}{2}\right) = \sum_{M' \leq x} H\left(\frac{x}{M'}\right)$.

The proof now follows as in Theorem 3.1, if we note that, if $k = 2^t \ell$, where $(\ell, 2) = 1$, then

$$\sum_{\substack{M' | k \\ (M' \text{ odd})}} \mu(M') = \sum_{m \mid \frac{k}{2^t}} \mu(m) = \begin{cases} 1, & \text{if } \ell = 1, \\ 0, & \text{if } \ell > 1, \end{cases}$$

so that, if k is odd,

$$\sum_{\substack{M' | k \\ (M' \text{ odd})}} \mu(M') = \left[\frac{1}{k} \right] ;$$

and also that the number of odd integers $\leq x$ is $\left[\frac{x+1}{2} \right]$.

Corollary.

$$\begin{aligned} \phi(N) = \sum_{M' \leq N/w} \mu(M') \left\{ \frac{\left[\frac{N}{M'} \right] \left[\frac{N}{M'} + 1 \right]}{2} - \frac{\left[\frac{N}{2M'} \right] \left[\frac{N}{2M'} + 1 \right]}{2} - \left(\sum_{I \leq N-1} \phi(I) \left(\frac{N+IM'}{2IM'} \right) \right. \right. \\ \left. \left. - \frac{N+vM'}{2vM'} \phi(v-1) \right) \right\} - \sum_{N/w+1 \leq K' \leq N/v} \phi\left(\frac{N}{K'}\right) \sum_{\substack{L' | K' \\ L' \leq N/w}} \mu(L'). \quad (3.26) \end{aligned}$$

For

$$\begin{aligned} \sum_{n \leq x} \phi\left(\frac{x}{n}\right) &= \sum_{n \leq x} \sum_{m \leq x/n} \phi(m) = \sum_{n \leq x} \phi(n) \left[\frac{x}{n} \right] \\ &= \sum_{n \leq x} \left[\frac{x}{n} \right] n \sum_{d | n} \frac{\mu(d)}{d} = \sum_{d \leq x} d \sum_{k \leq x/d} \mu(k) \left[\frac{x}{kd} \right] \\ &= \sum_{d \leq x} d = \frac{[x][x+1]}{2}. \end{aligned}$$

A preliminary program was used to obtain $\mu(n)$ and $\varphi(n)$ for $n = 1$ to 60 and $\Phi(n)$ for $n = 1$ to 3600 on cards as data to be read into the machine for the main program based on (3.26)

We note that, since we are just interested in determining the minimum value of $\frac{\Phi(x)}{x^2}$, we can reduce the checking, and hence the computer time, by observing

$$\frac{\Phi(2n)}{(2n)^2} < \frac{\Phi(2n-1)}{(2n-1)^2}, \quad (3.27)$$

$$\frac{\Phi(6n-2)}{(6n-2)^2} < \frac{\Phi(6n-4)}{(6n-4)^2}, \quad (3.28)$$

and

$$\frac{\Phi(30n-24)}{(30n-24)^2} < \frac{\Phi(30n-26)}{(30n-26)^2}. \quad (3.29)$$

We prove (3.27); the others are proven similarly. Now,

$$\frac{\Phi(2n)}{(2n)^2} < \frac{\Phi(2n-1)}{(2n-1)^2} \quad \text{if and only if} \quad \frac{\Phi(2n)}{(2n)^2} < \Phi(2n-1) \left(\frac{1}{(2n-1)^2} - \frac{1}{(2n)^2} \right),$$

i.e., if and only if, $\Phi(2n) < \Phi(2n-1) \frac{4n-1}{(2n-1)^2}$. Hence it suffices to prove

$$\Phi(2n) < \frac{2\Phi(2n-1)}{2n-1}.$$

But $\Phi(2n) \leq n-1$, while by (3.3),

$$\begin{aligned}
 \frac{2\Phi(2n-1)}{2n-1} &> \frac{6}{\pi^2} (2n-1) - 2 \log (2n-1) - 2 - \frac{3}{2(2n-1)} \\
 &= \frac{12}{\pi^2} n - 2 \log (2n-1) - (2 + 6/\pi^2) - \frac{3}{2(2n-1)} \\
 &> n \quad \text{for } n \geq 61 ;
 \end{aligned}$$

and (3.27) is readily verified for $n = 1, 2, \dots, 60$.

Hence, we need only examine nine residue classes modulo 30, namely 0, 6, 10, 12, 16, 18, 22, 24, 28.

We were able to determine all values of $n \leq 150,000$ for which $R(n)$ is negative. These 286 values are given in Appendix II.

APPENDIX I

Fortran IV programs for examining $\frac{1}{x^2} \sum_{n \leq x} \varphi(n) - \frac{3}{\pi^2}$.

1. $\mu(n)$ on cards for $1 \leq n \leq 60$. Uses $\sum_{n \leq x} M\left(\frac{x}{n}\right) = 1$.

Abstract

- Abstract: The purpose of this study was to investigate the effect of a 12-week training program on the physical fitness and health-related quality of life of sedentary middle-aged adults. The study was a randomized controlled trial. The participants were divided into two groups: the intervention group and the control group. The intervention group received a 12-week training program, while the control group remained sedentary. The primary outcome was the change in physical fitness, measured by the 6-minute walk test. The secondary outcome was the change in health-related quality of life, measured by the SF-36 questionnaire. The results showed that the intervention group had a significant improvement in physical fitness and health-related quality of life compared to the control group. The findings suggest that a 12-week training program can improve physical fitness and health-related quality of life in sedentary middle-aged adults.
1. Introduction: Physical fitness and health-related quality of life are important factors for overall health and well-being. Sedentary lifestyle is a major risk factor for chronic diseases and poor health-related quality of life. Therefore, it is important to investigate the effect of physical activity on these outcomes. This study aimed to investigate the effect of a 12-week training program on the physical fitness and health-related quality of life of sedentary middle-aged adults.
2. Methods: The study was a randomized controlled trial. The participants were divided into two groups: the intervention group and the control group. The intervention group received a 12-week training program, while the control group remained sedentary. The primary outcome was the change in physical fitness, measured by the 6-minute walk test. The secondary outcome was the change in health-related quality of life, measured by the SF-36 questionnaire.
3. Results: The results showed that the intervention group had a significant improvement in physical fitness and health-related quality of life compared to the control group. The findings suggest that a 12-week training program can improve physical fitness and health-related quality of life in sedentary middle-aged adults.
4. Conclusion: The findings of this study suggest that a 12-week training program can improve physical fitness and health-related quality of life in sedentary middle-aged adults. These findings have important implications for public health and clinical practice. Further research is needed to investigate the long-term effects of physical activity on physical fitness and health-related quality of life.
5. Limitations: The study had several limitations. First, the study was a short-term study, and the long-term effects of the training program were not investigated. Second, the study was conducted in a controlled setting, and the results may not be generalizable to real-world settings. Third, the study did not investigate the effect of the training program on other outcomes, such as blood pressure, cholesterol, and body weight.
6. Future Research: Future research should investigate the long-term effects of physical activity on physical fitness and health-related quality of life. Additionally, future research should investigate the effect of physical activity on other outcomes, such as blood pressure, cholesterol, and body weight. Finally, future research should investigate the effect of physical activity on different populations, such as older adults and people with chronic diseases.
